

PURPOSE

Total Cost of Ownership (TCO) Modeling is a tool that systematically accounts for all costs related to an information technology investment decision. TCO includes all costs, direct and indirect, incurred throughout the life cycle of an asset, including acquisition and procurement, operation and maintenance and end-of-life management. This document provides guidance on how to utilize TCO to make purchasing decisions for information technology products.

TOTAL COST OF OWNERSHIP MODELING

What is Total Cost of Ownership Modeling?

Comparing the cost of different information technology (IT) products and vendors can appear to be a simple task. However, many less obvious costs unrelated to the initial purchase price are frequently not considered and can strongly influence the "best choice." In fact, the initial procurement cost is a relatively small part of the total cost of owning and operating computers and most IT products.

Total Cost of Ownership (TCO) Modeling is a tool that systematically accounts for all costs related to an IT investment decision. TCO models were initially developed by Gartner Research in 1987 and are now widely accepted. Simply stated, TCO includes all costs, direct and indirect, incurred throughout the life cycle of an asset, including acquisition and procurement, operations and maintenance, and end-of-life management.

How does TCO Modeling differ from life cycle cost analysis or full cost accounting?

Life cycle cost analysis and full cost accounting are both systematic accounting approaches that seek to evaluate all costs associated with a product or practice, but TCO modeling is distinguished because it specifically evaluates IT products. These approaches can help organizations reduce net costs over time and document the benefits of practices like energy conservation and proper recycling.

Life cycle cost analysis is often applied to energy technologies and building projects. For example, a life cycle cost analysis can show that spending more initially on additional building insulation can produce a net savings (due to reduced heating and cooling costs) over the lifetime of a building.

The term full cost accounting is sometimes used interchangeably with life cycle cost analysis, but is typically used to evaluate ongoing programs. For example, the U.S. Environmental Protection Agency promotes full cost accounting as an appropriate tool for evaluating the costs of local solid waste management programs. It allows a municipality to account for such things as avoided disposal costs associated with recycling that otherwise might not be taken into account.

These systematic cost analysis tools are also sometimes used to identify externalities like the reduced pollution resulting from recycling or the purchase of electronic products with

reduced quantities of hazardous substances. While quantifying such environmental and societal benefits can be difficult, systematic approaches like TCO modeling provide a systematic framework for considering these types of costs and making better purchasing decisions.

Why should federal agencies use TCO?

Over time, a wide range of private and public sector organizations have come to view TCO as a valuable and widely accepted tool for managing IT spending. TCO modeling:

- Provides a consistent, systematic framework for comparing alternatives, increasing productivity and reducing overall costs over time.
- Establishes a standardized way to track and compare IT costs over time.
- Educates and raises awareness about the full costs of IT, showing that the initial IT procurement cost is a relatively small part of the full cost of ownership.

Federal agencies have additional incentives to use TCO:

- Issued in 1999, Executive Order 13123 (Section 401) states, "Agencies shall use life-cycle cost analysis in making decisions about their investment in products, services, construction and other projects to lower the Federal Government's costs and to reduce energy and water consumption."
- A wide range of federal policies and resources, such as Office of Management and Budget (OMB) Circular A-94: Guidelines and Discount Rates for Benefit-Cost Analysis of Federal Programs, encourage the use of life cycle cost analysis. Additionally, OMB Circular A-131 requires federal agencies to use "value engineering," a tool similar to TCO modeling.

TCO modeling is particularly useful for agencies that are partners in the Federal Electronics Challenge because it is an established, widely accepted method for evaluating costs related to all three phases of IT ownership: acquisition and procurement, operations and maintenance and end-of-life management. TCO modeling can help justify certain costs by showing, for example, that purchasing and appropriately using an ENERGY STAR® compliant computer can significantly reduce overall costs, or showing that the cost of properly reusing or recycling a computer might be only 1 percent or less of the full cost of ownership.

What is evaluated in a TCO Model?

While TCO was initially developed by Gartner Research, a wide range of firms now offer modeling software and other resources to assist in applying TCO. Historically, only simplified assumptions were used regarding environment-related costs such as energy savings and recycling. However, in 1993 Gartner Research adjusted its model to include the full range of costs associated with properly recycling, reusing, or disposing of electronics. Increasing design-for-environment and other environmental practices, like participation in the ENERGY STAR program, make analyzing environmental factors more important and easier. The following table summarizes the range of costs typically included in a TCO analysis.

Examples of Costs Typically Included in the Total Cost of Ownership

(Note: Costs are typically calculated on an annual basis by dividing by the expected product lifetime.)

Category	Examples of Costs
Acquisition and Procurement	<ul style="list-style-type: none"> • Administrative costs such as developing bid specs, evaluating proposals, gathering data, budgeting, and negotiating. • Researching and evaluating options such as upgrade, rebuy, lease, or purchase. • Contracts, tracking purchases, transfer and delivery. • Hardware (purchase or lease). Including personal computers (PCs), all peripherals, storage, networking, and other related equipment. • Spare systems and parts, annual supplies, and materials. • Software licenses.
Operations and Maintenance	<ul style="list-style-type: none"> • Administrative costs, including contract management, asset management, overseeing contractor services, a share of human resources, and other operating costs. • Vendor-contracted and/or in-house training of staff and IT personnel, product maintenance, and help desk support. • Information technology support such as database management, network management, and software management. • Retooling to accommodate new hardware and software. • Software and hardware upgrades over time. • Share of floor space, furniture, and other fixed office costs. • Internet and other network access costs. • Energy costs. • Training for IT staff and users. • Informal staff self-support of computer users. • Down time due to hardware/software malfunctions and/or user errors.
End-of-Life Management	<ul style="list-style-type: none"> • Administrative costs including asset management, documenting inventory, vendor contract procurement and management, and invoice payment. • Staging (removing and consolidating equipment). • Sanitizing hard drive and other storage media. • Testing and/or preparing for reuse, such as by reloading hard drive. • Providing follow-on support to employees or others purchasing used equipment. • Recycling/disposal fee and/or outsourcing fee. • Shipping. • Value of sold products and materials.

Typical Values for Total Cost of Ownership

When Gartner first developed TCO modeling, its conclusion that PCs can cost an organization up to \$10,000¹ per year was met with skepticism. Over time, the methodology and estimates of typical TCO values have been widely accepted. Although falling purchase prices and product improvements have steadily reduced total cost of ownership over time, studies still regularly show that PCs costing less than \$1,000 typically have a TCO of more than \$5,000 per year.² A \$200 printer could easily have an annual cost of more than \$1,000 when all the supplies and maintenance costs are included. Personal data assistants (PDAs) have a TCO of around \$3,000, comprised of hardware, software and network services (60 percent), operations (30 percent), and administration (10 percent). Adding a wireless modem with a TCO of \$1,392 can bring the PDA total cost to nearly \$4,400.³

While the specifics of TCO calculations vary, they generally show that the initial procurement price is a relatively low percentage of TCO. For example, according to IDC, a market-research firm, a PC's TCO in 1998 was \$5,236 per year, with only 15 percent of that attributable to procurement, 80 percent attributed to operations, and 5 percent to end-of-life management.⁴ Other estimates suggest that end-of-life management can be less than 1 percent of a PC's TCO.⁵

Some Limitations of TCO Modeling

Like any tool, TCO modeling does have limitations. For example:

- Although very likely to reduce long-term costs, TCO modeling itself initially adds cost by asking procurement decisionmakers to gather and consider more information.
- Since TCO modeling tracks long-term costs, capturing the benefits of TCO analysis in a single year's budget can be difficult.
- TCO modeling does not assess risk or how well a particular technology fits with an agency's strategic goals or needs.
- TCO modeling does not necessarily track environmental or social costs and benefits.

Notwithstanding its widespread acceptance and clear benefits, about 78 percent of IT administrators acknowledge they cannot document whether desktop costs are rising because they do not yet track the total cost of ownership.⁶
